
Retrofit Planner

Retrofit cost, saving and payback for one specific house, from four fields a mortgage lender already holds.

Lloyds Launch 2026 | Homes | RetrofitPlanner.co.uk

Built and run by one person. Plans to register in Q4 2026.

The incentive is funded. The decision is not.

- **£250 billion of home retrofit needed by 2050**

Lloyds' own estimate. 39% of its residential mortgages with a known EPC are band D, and 17% are E to G.

- **Just over 3,000 Eco Home Reward claims in 2025**

Against a book of millions. Up to £2,000 is available and almost nobody takes it.

- **EPCs do not measure what a house actually uses**

Lloyds 2025 sustainability report: EPCs capture neither actual energy use nor recent retrofit work, and a 2.0% gap to the financed emissions pathway is attributed to EPC data limits.

A household will not act on a cost and a saving. They act on how many years the money takes to come back, and which measure to do first. That is the number nobody is giving them.

Built from government microdata, published openly

DESNZ National Energy Efficiency Data-Framework 2026. 39,502 gas heated records with 2024 consumption, England and Wales. Median gas per property type and floor area band, calibrated to reproduce NEED published medians within 0.3%.

Four inputs. No smart meter, no survey, no account, no address.

property type | floor area or bedrooms | fabric condition | heating fuel

Method at </methodology/>. The model table itself is readable at </js/heat-model.js>.

Everything about it is checkable

- **The method is published, and enforced**

Comparable tools return a score or an estimate without saying how it was produced. This one publishes the model table and the method behind it, and two automated checks compare every figure on the site back against that table before anything goes live.

- **No AI, by choice, not anti AI**

A heat pump often costs five figures and a household lives with it for 15 years, so the method and the data behind the number should be visible, not just a confident answer. Deterministic arithmetic over public data, reproducible by hand, auditable by a model risk team.

- **It withholds the sale**

The boiler tool hides both the quote prompt and the lead capture form when the existing boiler is cheaper: at a £900 gas bill, 42 of its 120 input combinations. The solar tool tells 282 of 6,048 modelled cases the system never pays for itself.

Small, growing fast, and not yet validated

Monthly clicks from Google search

3.6

average Google position for the 4 bed heat pump cost guide, across 20,382 impressions

45,321

impressions in 22 days of September, against 11,801 in all of March

What I do not have, stated plainly

The site stores nothing on the device, so there is no count of calculator uses, no completion rate and no user feedback. And no model output has yet been checked against a real house quote or its metered consumption. Establishing that accuracy is the first thing a pilot should do.

12 weeks, one cohort, a falsifiable result

● Who

Mortgage customers at EPC band D or E, where the model is calibrated, against a matched holdout. Base rate near 0.1% means roughly 30,000 per arm.

● What they see

A payback figure and a ranked list of measures for their own home, inside a page Lloyds already runs.

● Measured by

Green additional borrowing drawn, and model accuracy against the customer's own annual kWh. No difference at 6 months means it did not work.

Commercially

Lloyds licences the model, IP stays with me. A four figure pilot fee, then a five figure annual licence. No revenue share and no referral links on a Lloyds page. It is a lookup table plus arithmetic, so no customer data needs to move.
